DEVELOPMENT OF A BASIC WEB BROWSER

INTRODUCTION

This chapter will provide an overview over the document and recapture the specified requirements that were requested.

1.1 DOCUMENT OVERVIEW

The document is divided into seven chapters that will describe different aspects of the developed program:

chapter 1 provides an overview over the document and the specified requirements, alongside certain assumptions that were made during the development.

chapter 2 will give a short outline of the requirements that were fulfilled, as well as mention added functionality that was not requested.

chapter 3 will provide a high level overview over the system's architecture and its sub modules.

chapter 4 is a short user guide that will describe the usage of the program by leading the reader through a selected choice of use cases to accomplish certain tasks.

chapter 5 will be based upon chapter 3 and provide an in-depth explanation of certain details of the implementation.

chapter 6 will outline how testing was performed and which cases have been covered.

chapter 7 will provide a reflection of the development process and the program and highlight areas of interest from the developer's point-of-view.

1.2 REMIT

The remit will summarize the requirements provided in the document *Systems Programming & Scripting (2010/2011) Assessment Two* and list all assumptions made in respect to a certain requirement.

For later reference in chapter 2 the requirements will be divided into seven groups: Web-Requirements (WR), Homepage-Requirements (HPR), Favourite-Requirements (FR), History-Requirements (HR), Printing-Requirements (PR), GUI-Requirements (GR), Additional-Requirements (AR)

WR01: Send Hypertext Transfer Protocol (HTTP) request message for typed URLs.

WR02: Receive HTTP responses for send requests.

WR03: Display received HyperText Markup Language (HTML)-code.

WR04: Display HTML for 200, 400, 403 and 404 headers.

HR01: Allow creation and editing of a homepage-URL.

HR02: Load homepage on application start-up.

FR01: Allow adding, deleting and editing of a URL to a list of favourites.

FR02: Allow the specification of a name for a favourite.

FR03: Request a favourite's URL when the favourite is activated.

FR04: Load all favourites on application start-up.

HR01: All pages that are requested shall be saved in a history.

HR02: Request a URL when an entry in the history is activated.

HR03: Load history on application start-up.

PR01: Allow printing of displayed web page.

GR01: Provide a GUI for the requirements.

GR02: Use menus, buttons, short cuts to increase *accessibility*[1].

AR01: Utilize multi-threading to keep application responsive.

AR02: Allow requesting of multiple web pages simultaneously.

---

1 Assumption: accessibility can be enhanced by using a standard layout common in Windows environments.

REQUIREMENT'S CHECKLIST

The following list shall provide an overview over the fulfilled requirements. The numbers correspond to those used in chapter 1.

WR01: Fulfilled by utilizing the HTTPWebRequest-classes of .NET.

WR02: Fulfilled by utilizing the HTTPWebResponse-classes of .NET.

WR03: Fulfilled in the GUI.

WR04: Fulfilled via error-handling.

HR01: Fulfilled as application setting [1].

HR02: Fulfilled.

FR01: Fulfilled [2]

FR02: Fulfilled.

FR03: Fulfilled. URL will open in current window.

FR04: Fulfilled.

HR01: Fulfilled.

HR02: Fulfilled. URL will open in current window.

HR03: Fulfilled [3].

PR01: Fulfilled. User can print the HTML-code of the current window.

GR01: Fulfilled. See chapter 4.

GR02: Fulfilled. See chapter 4.

AR01: Fulfilled. See chapter 3 and chapter 5 for further information.

AR02: Fulfilled.

---

1 A Windows conform standard path based on the user account is chosen to save the homepage and can not be adjusted.
2 A Windows conform standard path based on the user account is chosen to save the favourites and can not be adjusted.
3 A Windows conform standard path based on the user account is chosen to save the history and can not be adjusted.

DESIGN CONSIDERATIONS

This chapter provides a general overview of the application's design without explaining implementation details.

Therefore it will provide a general overview of the application's architecture and point out areas of interest in the design: these areas will describe the reasons the current approach has been chosen. If appropriate, the design patterns that were employed will be mentioned and described. Concrete implementation details will later be described in chapter 5.

3.1 ARCHITECTURAL OVERVIEW

The application was built with the MVP pattern as a basis for the architecture[1].

This way the program logic can be separated from the display logic. To achieve this, the view passes all calls to the presenter. The presenter routes them to the model if necessary.

All return values will be passed back to the presenter. The presenter will then decide what action the view needs to take according to the received values. These action will be communicated via an interface.

This leads to a **decoupling** between the view and the model and allows the presenter to be reusable across multiple views.

A schematic visualisation of this pattern looks like this:
Figure 1: MVP-Pattern

---

[1] Further information can be found at MVP-Pattern (`http://msdn.microsoft.com/en-us/magazine/cc188690.aspx`)

This already show the division into two distinct projects:

GUI: Hosts the GUI implemented in WinForms. This includes all display-related logic: perform actions based on events, display and hide controls, respond to clicks.

LOGIC: Hosts the *business*-logic, the interfaces and the presenters.

As can already be inferred from the short description, most of the application's logic is based in the logic project, which (excluding the view interfaces) encompasses the following classes:

Figure 2: Classes of the logic project.

The following design decisions were made while implementing the application:

3.2 SEPARATE CHANGE

Special attention should be paid to the classes `FavouriteHandler` and `HistoryHandler`. From a design point-of-view, they provide the presenters that are utilizing them with a facade to the data-classes `History` and `Favourite`.

To centralize changes and prevent data loss due to multiple handlers, both objects were implemented via the `Singleton` pattern, ensuring only one object is present at any given time. This way all presenters will modify the same data.

Moreover the handler classes implement an `Observer` pattern to notify the relevant presenter about any changes that occur in the data. This way the presenter can make certain that the view is always displaying accurate data. This was necessary as the `PagePresenter` and the `HistoryPresenter` both operate on the history-data: the `PagePresenter` adds every visited page to the history, whereas the `HistoryPresenter` ensures that the History is correctly displayed in the view.

The same principle applies in the case of the `FavouritePresenter` and the `FavouritesPresenter`. The first one adds and edits one single `Favourite`, whereas the second presenter handles the display of multiple `Favourites` and the deletion logic.

3.3 LOOSE COUPLING

To provide a loosely coupled application that may be enhanced with little effort at a later time, the communication between distinct logical groups in the application was implemented via interfaces.

The logical groups (that are not denoted separately in the projects) are:

- View: Realized in a separate project.

- Logic: Realized in the logic project.

- Persistence: Realized in the logic project in the classes `ISerialiser` and the concrete implementations of the interface.

As already shown in the MVP pattern the presenter $\longleftrightarrow$ view communication is decoupled via interfaces. Moreover the logic $\longleftrightarrow$ persistence communication is decoupled via the `ISerialiser` interface as well.

3.4 THREADING

To fulfil the requirements `AR01` and `AR02` multi threading was introduced in the application when a web-page is requested.

Therefore the request will be carried out in an `asynchronous` thread.

As the view should not be concerned about concrete implementation choices, the decision was made, to introduce multi-threading in the **logic!** (**logic!**) project. It is implemented in the `TextPage`-presenter. This way the application will not loose one of its core-functions should the customer decide to exchange the GUI.

However, certain changes had to be implemented in the GUI to support multi-threading in a WinForms application (see **??** for the details): should the GUI be exchanged these problems might need to be taken into account again.

USER GUIDE

The application provides five functions:

- Requesting and displaying web-pages.

- Managing the history of requested web-pages.

- Managing user-defined favourites.

- Managing a user-defined home-page.

- Allow printing of the currently displayed web-page.

These functions shall be explained in this chapter.

4.1 REQUESTING A WEB-PAGE

Upon starting the application the user will see the following window:
Figure 3: The application's main window.

To request a web-page the user must enter the desired address in the Address text-box and then press the Go-button ( ).

The format of the entered address will be verified. It must match the following pattern[1]:

```
1 http://[www.]address.domain[/url-path]
```

Should the entered address not match the given format, the program will notify the user about the error by displaying a message-box:
Figure 4: Error message due to invalid url.

When the url is valid the browser will display the HTML-code in the current tab:
Figure 5: Browser displaying the current web-page.

To request multiple pages simultaneously it is possible to utilize tabs:

To create a new tab, the user simply presses the AddTab-button (). This will create new (and empty) tab-page.

---

1 Parts in square-brackets may not be required for all web-pages.

Should the user want to close a tab it is necessary to select the tab that should be closed and press the RemoveTab-button (⬜).

4.2 MANAGING THE HISTORY

Every web-page requested by the user will be saved in the history.

The history can be accessed by pressing the History-button (⬛) in the MenuBar under Edit → History.

This will display a panel in the main window of the application that shows the History in one and the Favourites in another tab:
Figure 6: The history tab.

As can be seen the history is ordered in a tree-structure that groups together addresses that were visited on the same day.

To visit one of the pages the user just clicks one of the links in the tree and the application will open the requested page in the current tab.

As the history is prone to become quite huge it is possible to clear it. To perform this action the user selects the ClearHistory-option (⬛) from the MenuBar. This operation can be found under Edit → History → Clear.

4.3 MANAGING FAVOURITES

The application allows a user to add, edit and delete favourites.

There are two ways to add a favourite: either the user clicks the AddFavourite-button (⬛) in the AddressBar or in the ContextMenu of the Favourites-List.

To open the `Favourites-List` the user clicks the `Favourite`-button in the `MenuBar`: `Edit → Favourites`.

This will open the Favourites-List:
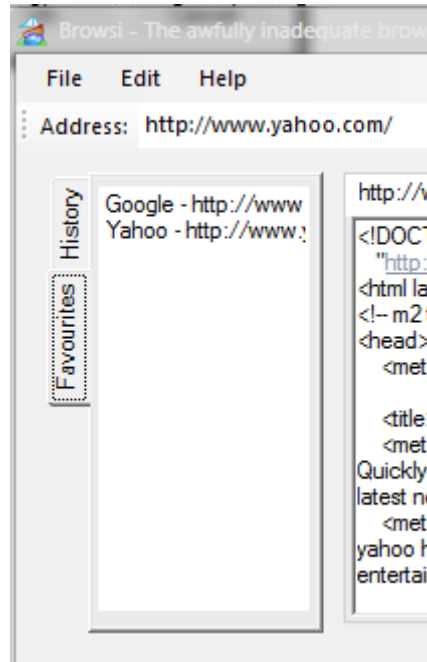

Figure 7: The favourites tab.

When the user right-clicks in this list a context-menu will open that will allow the user to either `Add`, `Edit` or `Delete` a favourite.
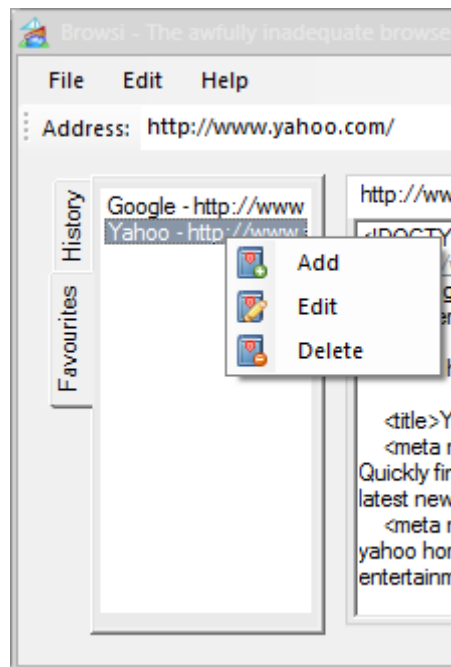

Figure 8: The context menu.

When the user decides to add a favourite, a new window will pop-up that asks him to enter a name and a URL for the favourite. The URL will, by default, be set to the address of the currently activated tab.
Figure 9: Add-favourite window.

4.4 SETTING A HOME-PAGE

It is also possible to set a home-page that will be opened as soon as the application is started.

Therefore the user opens the Settings-Window by clicking on the Settings-button (🔧) found under File → Settings.

This will open the Settings-Window that allows the user to enter a home-page:
Figure 10: Settings window.

4.5 PRINTING A WEB-PAGE

The last function the user can perform is to print a web-page.

Therefore the tab that should be printed needs to be selected and then the Print-button () needs to be clicked (File → Print).

This will display a printing-dialog that allows the user to tweak desired settings. Clicking the OK-button will the print the HTML of the current tab.

DEVELOPER GUIDE

This chapter will guide the reader through the different requirements and their implementation in the application.

Having finished with the requirements a section highlighting certain problems or special cases that were encountered during the development will be described.

5.1 IMPLEMENTATION OF THE REQUIREMENTS

5.1.1 *Web-requirements*

Requirements `WR01`, `WR02` and `WR03` are implemented in the `PageHandler`-class:

It requests a provided URL via its `FetchUrl()`-method that will return a `SimpleWebResponse`-object. The `SimpleWebResponse`-object encapsulates just a title, body and a url - all elements needed to display a web-page.

To fulfil requirement `WR04` it is necessary to assign a `WebResponse` after catching an exception that is thrown by the `.NET`-framework if a response does not contain a 200 (OK)-message:

```
try
{
        this.Request = WebRequest.Create(this.RequestUrl);
        this.Response = this.Request.GetResponse();
}
catch (WebException e)
{
        logger.Error("WebException ({0}) occured when fetching the url: {1}", e.Message
            , this.RequestUrl);
        this.Response = e.Response;
}
```

Listing 1: Fetching URLs with error-codes

`WR04` is implemented in the `PagePresenter`: the page-presenter starts a `FetchUrl()`-method-call via an asynchronous delegate and provides a callback-mechanism to its `Done()`-method.

```
Func<SimpleWebResponse> method = pageHandler.FetchUrl;
method.BeginInvoke(Done, method);
```

Listing 2: Fetching URLs with error-codes

When the `Done()`-method is invoked, the presenter calls the view's `DisplayWebpage()`-method that prints the received HTML-code[1].

5.1.2 *Homepage-Requirements*

The homepage is saved as a simple string. This leads to the possibility to save it via the `ApplicationSettings` - a facility provided by the `.NET` framework.

The only problem in this implementation is the fact that only the `WinForms` project is allowed to access the application-settings[2].

Due to this reason the code to write the string is located in the `SettingsWindow`:

```
private void SaveSettings(String homePage)
    {
        Settings settings = Settings.Default;
        settings.Homepage = homePage;
        settings.Save();
    }
```

5.1.3 *Favourite-requirements*

The requirements `FR01` and `FR02` were implemented in the `Favourite` and `FavouriteHandler`-classes.

Apart from handling the adding (`AddEntry()`), deleting (`DeleteFavourite()`) and editing (`EditFavourite()`) of favourites, the `FavouriteHandler` also handles the saving (`SaveFavourite()`) and loading (`LoadFavourites()`) of favourites.

Requirement `FR04` is fulfilled by the `FavouritePresenter`: upon creation the presenter determines the file-path for the favourite file and sets it in the `FavouriteHandler`:

```
private void SetUpHandler()
    {
        String appFolder = Environment.GetFolderPath(Environment.SpecialFolder.
            ApplicationData);
        String history = "Favourites.xml";
        this._FavouriteHandler.SetFilePath(Path.Combine(appFolder, history));
        this._FavouriteHandler.LoadFavourite();
    }
```

This approach was chosen to keep the `FavouriteHandler` reusable, whereas the presenter can be considered application-specific.

---

1 See **??** to see details for the necessary view-implementation.

2 It would be possible to provide a reference to the GUI-project in the logic-project. However this would lead to a dependency between the logic-project and the GUI - a circumstance that should be prevented by utilizing the MVP-pattern. Due to this fact the GUI writes the application settings and the logic stays independent from the GUI.

Requirement FR03 was implemented in the GUI: when the user clicks an element in the favourite-list, the element is determined and the url of the favourite is written into the URL-text-field. After this has happened, a standard URL-request is issued and the URL will be displayed in the active tab.

5.1.4 *History-requirements*

The implementation of the history-requirements is similar to the those of the favourites.

The main-classes are History and HistoryHandler, whereas the loading on start-up is provided by the HistoryPresenter.

```
1  private void SetUpHandler()
2        {
3            String appFolder = Environment.GetFolderPath(Environment.SpecialFolder.
                  ApplicationData);
4            String history = "History.xml";
5            this._HistoryHandler.SetFilePath(Path.Combine(appFolder, history));
6            this._HistoryHandler.LoadHistory();
7        }
```

The loading of a URL on user-interaction is implemented in the GUI via a NodeMouseClick-Event on the History-TreeView.

5.1.5 *Printing-requirements*

Requirement PR01 was implemented in the MainWindow and the PrintPresenter-classes.

The PrintPresenter's Print()-method will be called for every page that needs to be printed.

The method will determine the size of the String that shall be printed and set the HasMorePages-property to true if the String would not fit onto one page:

```
1  public void Print(System.Drawing.Printing.PrintPageEventArgs e)
2        {
3
4            Font font = _PrintView.CurrentFont;
5            int charactersOnPage = 0;
6            int linesPerPage = 0;
7
8            // Sets the value of charactersOnPage to the number of characters
9            // of PrintString that will fit within the bounds of the page.
10           e.Graphics.MeasureString(PrintString, font,
11               e.MarginBounds.Size, StringFormat.GenericTypographic,
12               out charactersOnPage, out linesPerPage);
13
14           // Draws the string within the bounds of the page
```

```
15              e.Graphics.DrawString(PrintString, font, Brushes.Black,
16                  e.MarginBounds, StringFormat.GenericTypographic);
17
18              // Remove the portion of the string that has been printed.
19              PrintString = PrintString.Substring(charactersOnPage);
20
21              // Check to see if more pages are to be printed.
22              e.HasMorePages = (PrintString.Length > 0);
23          }
```

5.1.6 *User-interface requirements*

All actions can be performed via a GUI: see chapter 4 for an introduction of how to use the provided GUI.

As the GUI was implemented via the `WinForms` designer and all actions that are not just altering the GUI are passed to the presenters, no significant logic that has not already been mentioned is implemented in the GUI.

Due to this fact no more implementation-details about the requirements `GR01` and `GR02` will be described.

5.2 DETAILS OF THE IMPLEMENTATION

Apart from just providing an overview over the requirements and their corresponding implementation, this section will provide an overview over certain areas of code that might be hard to understand without further explanation, but are not directly linked to a certain requirement.

5.2.1 *View*

All GUI classes have a common ancestor: the class `ThreadingView`:
Figure 11: GUI class hierarchy

Due to this approach all classes are able to use the `UpdateUI()`-method of this class when another thread wants to alter a GUI-control:

```
protected void UpdateUI(MethodInvoker uiDelegate)
    {
        if (InvokeRequired)
        {
            this.Invoke(uiDelegate);
        }
        else
        {
            uiDelegate();
        }
    }
```

This is necessary as only the thread that created a GUI-component is allowed to update it. Via `InvokeRequired` it is possible to check if another thread tries to modify the component (returns `true` if another thread wants to modify it, `false` otherwise).

In the current application this behaviour might occur when the page-request-thread calls the `PagePresenter`'s `done()` method and the presenter tries to force the view to display the web-page. To prevent an exception from ocurring the code to update the GUI-component is called like this:

```
public void DisplayWebPage(SimpleWebResponse response)
    {
        foreach (TabPage page in this.webSitesTabControl.TabPages)
        {
            if (page.Name.Equals(response.Url))
            {
                MethodInvoker uiDelegate = delegate
                {
                    page.Controls[0].Text = response.Html;
```

```
10                    page.Text = response.Title;
11                };
12                UpdateUI(uiDelegate);
13            }
14        }
15    }
```

This way the GUI-thread will alter the component.

5.2.2 *Observer-pattern*

As already mentioned in section 3.2 the observer pattern is used to keep the different presenters up-to-date. Namely this approach concerns the Favourite- and HistoryHandlers and their respective presenters.

However the implementation was not performed utilizing multiple classes as described in Gamma et al. (1994), but by utilizing .NET specific concepts like delegates.

Therefore the handlers declare a delegate that the observers can use. Moreover an event needs to be declared that will chain the multiple methods of the observers, so that every observer will be notified of occuring changes.

The concrete implementation-stubs look like this:

```
1  public delegate void ChangeHandler(object subject);
2  public event ChangeHandler ChangeEvent;
```

Listing 3: Declaration of delegate and event.

When a change occurs the Notify()-method will be called that notifies all observers of the change:

```
1  private void Notify()
2  {
3      if (ChangeEvent != null)
4      {
5          ChangeEvent(this);
6      }
7  }
```

Listing 4: Notifying observers.

The observers can then handle the change in their subscribed method.
To subscribe, the following chaining to the event is sufficient:

```
1  this._HistoryHandler.ChangeEvent += new HistoryHandler.ChangeHandler(this.Update);
```

Listing 5: Registering as an observer.

After that the Update()-method can handle all changes:

```
1  public void Update(object subject)
2  {
3        if (subject is HistoryHandler)
4        {
5            HistoryHandler histhandler = subject as HistoryHandler;
6            this._HistoryView.DisplayHistory(histhandler.History);
7        }
8  }
```

5.2.3 *Singleton-pattern*

Another pattern that was used in the `Handler`-classes was the `Singleton`-pattern.

The pattern was employed due to the fact that two different presenters access each handler and both presenter need to modify the same data.

However, the implementation of the singleton is the standard one found in many object-oriented languages:

```
1  private static HistoryHandler _Instance;
2
3  /// <summary>
4  /// Gets the instance.
5  /// </summary>
6  /// <value>The instance.</value>
7  public static HistoryHandler Instance
8  {
9          get
10         {
11             if (_Instance == null)
12             {
13                 lock (lockObject)
14                 {
15                     if (_Instance == null)
16                     {
17                         _Instance = new HistoryHandler();
18                     }
19                 }
20             }
21             return _Instance;
22         }
23     }
```

5.2.4 *Serialisation*

The last thing to be pointed out is the implementation of the persistence-functionality.

The two classes responsible to persist the data (`FavouriteHandler` and `HistoryHandler`) refer to the persisting class only via its interface (`ISerialiser<T>`) making use of

polymorphism. This way the implementation can easily be swapped out to support a different kind of serialisation.

In the delivered application the persisting of the history and the favourites is performed via the Extensible Markup Language (XML)-format. Should another format be used it suffices to create a new class that implements the `ISerialiser<T>`-interface and provide the new mechanism for serialisation.

Then it is enough to instantiate an instance of this new class in the two handlers.

Due to the fact that the current implementation utilises `Generics` one class can be used for multiple classes.

However, while implementing the application certain limitations of the `.NET`-framework made it necessary to "implement"[3] a new `SerializableDictionary`-class, as the dictionaries provided by the .NET framework are not serialisable to an XML-representation.

---

3 The used implementation was taken from http://weblogs.asp.net/pwelter34/archive/2006/05/03/444961.aspx - as stated in the comments this implementation was tested against 30 test-cases and due to this fact preferred to a self-implemented one.

6

TESTING

The testing of the application was performed in two stages:

- In early development stages unit-tests were written for the base classes (History, Favourite, Serialiser, PageHandler).

- After chaining the application parts together the applications correct behaviour was mainly tested by using the application. This was necessary as unit-testing GUI and multi-threaded code is extremely difficult.

6.1 UNIT-TESTS

The unit-tests that were written can be seen in section A.3.

To run the test-cases the NUnit-framework (`http://www.nunit.org/`) is needed. They mainly cover the exception prone cases of the basic-classes.

6.2 ACCEPTANCE-TESTS

7

CONCLUSIONS

Part II

APPENDIX

APPENDIX: SOURCE CODE

A.1   GUI

Project: GUI

```csharp
1  ï»¿using System;
2  using System.Collections.Generic;
3  using System.Linq;
4  using System.Text;
5  using System.Windows.Forms;
6
7  namespace Assessment_Two
8  {
9      /// <summary>
10     /// Class provides all inheriting views with delegate mechanism to allow threads
            to redraw elements on the main thread.
11     /// </summary>
12     public class ThreadingView : Form
13     {
14         protected void UpdateUI(MethodInvoker uiDelegate)
15         {
16             if (InvokeRequired)
17             {
18                 this.Invoke(uiDelegate);
19             }
20             else
21             {
22                 uiDelegate();
23             }
24         }
25     }
26 }
```
